The authors present a method for determining the optimal interval for preventive periodical maintenance and an optimal diagnostic parameter for predictive maintenance/replacement. Additionally, the authors raise the question: how does preventive maintenance influence the probability of failure and the operational reliability of system elements that have undergone preventive periodical maintenance? They answer the question using analytical and simulation computing approaches. The results are in quantitative form, giving relationships between preventive maintenance intervals and reliability functions. Examples demonstrate suitability of the method for typical engineering objects using a three parameters Weibull distribution. Application of the method is of substantial benefit to both the manufacturer and the user of technical equipment.

**Keywords:** preventive maintenance, predictive maintenance, maintenance interval optimization, reliability improvement.
It determines the optimal preventive maintenance and replacement schedule of the system.

The paper [16] takes into account degradation modeling and maintenance policy for a two-stage degradation system, which degradation process is nonlinear and degradation rate is change over time in both stages. Influence analysis of different model parameter and maintenance policy is studied in numerical examples with results that the proposed optimal maintenance policy can help to reduce the mean cost rate.

In the paper, [17] the authors proposed a hybrid imperfect maintenance model with random adjustment-reduction parameters and a maintenance policy. Furthermore, a numerical example and an example of the fuel injection pump of diesel engines are carried out and presented to illustrate the proposed method.

A mathematical model of optimization of maintenance intervals having regard to the risk is presented in the paper [18]. Precise calculations were made for steam turbines that operate in power units.

Maintenance can represent a significant portion of the cost in asset intensive organizations, as breakdowns have an impact on the capacity, quality and cost of operation [21]. However, the formulation of a maintenance strategy depends on a number of factors, including the cost of down time, reliability characteristics and redundancy of assets. Consequently, the balance between preventive maintenance (PM) and corrective maintenance (CM) for minimizing costs varies between organizations and assets. Nevertheless, there are some rules of thumb on the balance between PM and CM, such as the 80/20 rule.

In the paper [22], an approach is presented, which allows evaluation of various possible maintenance scenarios with respect to both reliability and economic criteria. Authors included three deterioration states (D1 ÷ D3) and three repairs: minor (index = 1), medium (2) and major (3), but in real machine operation it is difficult to define these general states and repairs exactly.

In the paper [23] a double-fold Weibull competing risk model using the real failure data from railway operation, was developed for the engine system of a diesel locomotive and its current maintenance. Results show that the maintenance period varies widely between winter and summer, and that optimized maintenance can increase the availability and decrease cost more than the existing policy.

The paper [7] is a very large review on machinery diagnostics and prognostics implementing condition-based maintenance using 271 references and other reviews in the paper [19] using 104 references which point to future perspectives on maintenance optimization. These two references [7, 19] fully support the authors method, from data collection through data processing to optimal maintenance decision making.

These references proposed interesting models regarding concrete application on particular technical systems with different structures and as well a general solution. The authors did not find in the review, a simple model of predictive maintenance optimization for industrial practice and no idea that preventive maintenance improves reliability including utilization of a three parameters Weibull distribution. According to authors’ experiences from different fields of industry, maintenance managers need simple and general methods for design of maintenance programs and policies optimization. Therefore, the objective of this paper is to contribute to the optimization of predictive maintenance with a new simple semi-stochastic model. A further objective was to give maintenance staff evidence that preventive maintenance improves operational reliability based on a mathematical theory of reliability [1, 20] and authors works [9, 12, 13]. Finally, all models are demonstrated using numerical simulation with a three parameters Weibull distribution supported by table processor Excel.

2. Optimization of predictive maintenance

In discussing machine maintenance strategy, it is customary to distinguish between the following methods (policies) [3]:

a) corrective maintenance - maintenance carried out after fault recognition and intended to put an item into a state in which it can perform a required function,

b) preventive maintenance - maintenance carried out at predetermined intervals or according to prescribed criteria and intended to reduce the probability of failure or the degradation of the functioning of an item; following policies c), d) and e) are also preventive maintenance,

c) predetermined maintenance, preventive maintenance carried out in accordance with established intervals of time or number of units of use but without previous condition investigation,

d) condition based maintenance - preventive maintenance which includes a combination of condition monitoring and/or inspection and/or testing, analysis and the ensuing maintenance actions; the condition monitoring and/or inspection and/or testing may be scheduled, on request or continuous,

e) predictive maintenance - condition based maintenance carried out following a forecast derived from repeated analysis or known characteristics and evaluation of the significant parameters of the degradation of the item.

The proposed model of predictive maintenance optimization is based on minimizing of unit maintenance, diagnostics and failure risk cost of a component [1]:

\[ c(S_p) = \frac{C_{pr} + L_f F(S_p)}{t(S_p)} + c_d \]  

where \( S_p \) is a diagnostic signal for predictive maintenance; diagnostic signal is allowed to be a random variable, \( C_{pr} \) is cost of preventive maintenance, \( L_f \) is loss due to failure risk ( \( L_f F(S_p) \) ); loss due to failure risk can be calculated as a difference between cost of corrective maintenance and cost of preventive maintenance, it means \( L_f = C_{pr} - C_{pm} F(S_p) \) is probability of failure depending on diagnostic signal \( S_p \), \( c_d \) denotes unit costs of condition monitoring to obtain diagnostic signal \( S_p \), \( t(S_p) \) is the mean time corresponding to diagnostic signal \( S_p \) which can be determined from operational data using the formula:

\[ t(S_p) = \frac{1}{n} \left( \sum_{i=1}^{m(S_p)} t(S_p) + \sum_{j=1}^{n-m(S_p)} t(S_p) \right) \]

where \( t(S_p) \) denotes the operating time of the \( i \)th object surviving at the level \( S_p \) and \( t(S_p) \) denotes the time to failure of the \( j \)th object which failed before reaching the state \( S_p \) \( m(S_p) \) is the number of objects reaching state \( S_p \) without failure and \( n \) is the total number of objects in the investigated population. To obtain these data it is necessary to carry out an operational observation – life test of objects population including on-line diagnostic measurement till failure or at least diagnostic signals \( S_p \) closely before failure occurs. In the first case, it is easy to apply equation (2) and probability of failure (distribution function) \( F(S_p) \) can be obtained by means of diagnostic signals \( S_p \) shortly before failure. If there are only recognized diagnostic signals (technical states) closely before failures, it is necessary to calculate operating time related to selected diagnostic signal \( S_p \) which is used as an indicator for predictive maintenance of an object.

For calculation of mean operating time, versus diagnostic signal for predictive maintenance \( t(S_p) \), authors use a simplified model in which the technical state degradation (a change of diagnostic signal)
runs along a straight line from start state $S_{pl}$ to limit value of technical state (to failure) $S_{pf}<S_{pl}$ i-th object. The accuracy of this approximation from point of technical solution is sufficient. Calculation of the $t_i(S_{pl})$ is carried out in a case of the $S_{pl} < S_{pf}$ according to equation (3):

$$t_i(S_{pl}) = t_i(S_{pf}) = \frac{\frac{S_{pl} - S_{p}}{t_i(S_{pf}) - S_{p}}}{\frac{S_{pf} - S_{p}}{S_{pf} - S_{p}}} ,$$

(3)

Fig. 1. Principle of input data determination for calculation of mean operating time versus diagnostic signal for predictive maintenance $\tilde{t}(S_{pl})$

If $S_{pl} \geq S_{pf}$, the operating time to failure of the jth object which failed before reaching the diagnostic signal $S_{pf}$, we can read directly from the database of operating time to failure of the jth object which failed before reaching the diagnostic signal $t_j(S_{pl})$. Interpretation of these input data is clear from Fig. 1.

Unit costs of preventive maintenance and failure risk versus diagnostic signal for predictive maintenance $c_{fi}$ (for $c(S_{pl}) = minimum$) we can calculate, using equation (4):

$$c(S_{pl}) = c_{pe} + \frac{L_jF(S_{pl})}{\tilde{t}(S_{pl})} + c_d = \frac{c_{pe} + L_jF(S_{pl})}{\frac{1}{n} \sum_{i=1}^{m(S_{pl})} t_i(S_{pl}) + \frac{1}{n} \sum_{j=1}^{m(S_{pl})} t_j(S_{pl})}$$

(4)

For a proposed model of predictive maintenance optimization (4) it is necessary to obtain or calculate input data as follows:

a) cost of preventive maintenance $C_{pe}$

b) losses due to failure risk $L_j$

c) probability of failure versus diagnostic signal for predictive maintenance $F(S_{pl})$

d) mean operating time versus diagnostic signal for predictive maintenance $\tilde{t}(S_{pl})$

e) unit cost of diagnostics (condition monitoring) $c_d$

f) diagnostic signal for predictive maintenance $S_{pl}$

Optimal predictive dispositional operating time $t_d(S_{po})$ from actual operating time $t(S)$ in decision making state to optimal operating time $t(S_{po})$ for predictive maintenance (restoration, replacement) is calculated from equation

$$t_d(S_{po}) = t(S_{po}) - t(S)$$

(5)

3. Calculation of mean life and reliability functions of preventive predetermined maintained objects

If we should prove that preventive predetermined maintenance increases operational reliability, we must calculate reliability function of object predetermined maintained in operating time $t_p$ and its mean life $\bar{E}T$ of preventively predetermined maintained objects in time $t_p$ compared with corrective maintenance of the same object.

Let us monitor a series of objects that underwent preventive predetermined maintenance (were replaced) after time interval $t_p$ using a new object with the same reliability properties. Also, let us suppose that its durability is characterized by a random variable $X$ with a continuous density function $f$ and distribution function $F$.

Object reliability can be improved during operation by preventive predetermined replacement at time $t_p$. Durability of k-th component is also described by a random variable $X_k$ with the same density function $f$ and distribution function $F$. We suppose that random variables $X_1, X_2, ...$ are independent.

Let us denote by $T$ a random variable which describes the life of preventively predetermined replaced objects. Further, we derive the formula of the density function $f_T$ and the distribution function $F_T$ for the random variable $T$. We are particularly interested in the mean value $\bar{E}T$.

Let us denote $p = P[X_i < t_p], q = P[X_i \geq t_p] = 1 - p$ and

$$I = \int_0^{t_p} f(x)dx.$$ We express the random variable $T$ using $X_i$ in the following way:

$$T = \begin{cases} X_1 & \text{for } X_i < t_p \\ t_p + X_1 & \text{for } X_i^{t_p}, X_i^{t_p} < t_p \\ 2t_p + X_1 & \text{for } X_i^{t_p}, X_i^{t_p}, X_i^{t_p} < t_p \\ .......... & \text{for } X_i^{t_p}, X_i^{t_p}, X_i^{t_p}, ..., X_i^{t_p}, X_i^{t_p} < t_p. \end{cases}$$

With respect to independence $X_i, X_2, ...$, from the total probability theorem it holds for arbitrary $x \in (0;\infty)$:

$$F_T(x) = P[T < x] = \begin{cases} X_1 & \text{for } X_i < t_p \\ t_p + X_1 & \text{for } X_i^{t_p}, X_i^{t_p} < t_p \\ 2t_p + X_1 & \text{for } X_i^{t_p}, X_i^{t_p}, X_i^{t_p} < t_p \\ .......... & \text{for } X_i^{t_p}, X_i^{t_p}, X_i^{t_p}, ..., X_i^{t_p}, X_i^{t_p} < t_p. \end{cases}$$

(6)

Further, we calculate according to the definition of conditional probability with respect to the independence of $X_i, X_2, ...$

$$P[T < x / X_i^{t_p}, ..., X_i^{t_p}, X_i^{t_p} < t_p] = \begin{cases} P[X_i < t_p / X_i^{t_p}, ..., X_i^{t_p}, X_i^{t_p} < t_p] = P[X_i < x / X_i^{t_p}, X_i^{t_p} < t_p] & \text{for } x < X_i^{t_p}, X_i^{t_p}, X_i^{t_p} < t_p \\ P[X_i^{t_p}, ..., X_i^{t_p}, X_i^{t_p} < t_p] & \text{for } X_i^{t_p}, X_i^{t_p}, X_i^{t_p} < t_p. \end{cases}$$

(7)
After substitution (7) into equation (6) we obtain:

\[ F_T(x) = P[T < x] = \sum_{k=0}^{\infty} P[X_{k+1} < \min(x - k t_p, t_p)] = \sum_{k=0}^{\infty} F(\min(x - k t_p, t_p)) q^k \]

It is possible to itemize the distribution function \( F_T \) around the following intervals:

\[
F_T(x) = \begin{cases} 
F(x) & \text{on } (0; t_p) \\
F'(t_p) + q F(x - t_p) & \text{on } (t_p; 2t_p) \\
q^2 F(x - 2t_p) & \text{on } (2t_p; 3t_p) \\
& \ldots 
\end{cases}
\] (8)

Last, using a modified equation (8), we calculate the failure probability \( F_T(t) \) and the reliability function \( R_T(t) \) for the components that underwent preventive predetermined maintenance:

\[ F_T(t) = F(t_p) + R(t_p) F(t- t_p) + R^2(t_p) F(t-2 t_p) + R^3(t_p) F(t-3 t_p) + \ldots \] (9)

and

\[ R_T(t) = 1 - F_T(t) \] (10)

We obtain density function \( f_T \) by differentiation of \( F_T \):

\[
f_T(x) = \begin{cases} 
- \frac{\partial F(x)}{dx} & \text{on } (0; t_p) \\
q f(x - t_p) & \text{on } (t_p; 2t_p) \\
q^2 f(x - 2t_p) & \text{on } (2t_p; 3t_p) \\
& \ldots 
\end{cases}
\] (11)

Finally, we calculate the mean value of life (sum of particular operating time) for objects that underwent preventive predetermined replacement:

\[
ET = \sum_{k=0}^{\infty} \int_0^{t_p} f(x)dx = \sum_{k=0}^{\infty} \int_0^{t_p} k! f(x)dx = \sum_{k=0}^{\infty} \int_0^{t_p} k! f(x)dx \sum_{k=0}^{\infty} k! q^k = \int_0^{t_p} f(x)dx \sum_{k=0}^{\infty} k! q^k = \int_0^{t_p} f(x)dx \sum_{k=0}^{\infty} \frac{k!}{k!} q^k = \int_0^{t_p} f(x)dx \sum_{k=0}^{\infty} \frac{1}{k!} q^k \frac{1}{(1-q)^2} = \int_0^{t_p} f(x)dx \sum_{k=0}^{\infty} \frac{1}{k!} q^k (1-q)^{-2} = \frac{1}{1-q} q + pt_F \frac{1}{(1-q)^2} = \frac{1}{1-q} \frac{q}{p},
\] (12)

we have used the formula for the sum of the geometrical series \( 1 + q + q^2 + \ldots \) and from this formula through differentiation we have obtained the derived formula

\[ \sum_{k=0}^{\infty} k! q^k = 1/(1-q)^2. \]

Integral \( I \) can be modified using integration by parts:

\[
I = \int_0^{t_p} f(x)dx = t_p F'(t_p) - \int_0^{t_p} F(x)dx = \]

\[= t_p F'(t_p) - t_p + \int_0^{t_p} R(x)dx = -q t_p + \int_0^{t_p} R(x)dx, \] (13)

where \( R(x) = 1 - F(x) \) is reliability function.

For mean value \( ET \) of the life of preventively predetermined maintained objects at time \( t_p \) we obtain the following equation:

\[
ET = \frac{1}{F_t(t_p)} \int_0^{t_p} R(x)dx = \frac{\int_0^{t_p} R(x)dx}{1 - R(t_p)} \] (14)

From equation (14) it is clear that mean life of preventive predetermined maintained objects \( ET > \int_0^{t_p} R(x)dx \) (mean life of corrective maintained objects) for \( t_p < \infty \). This fact proves that preventive predetermined maintenance increases operational reliability of objects comparing with corrective maintenance.

Optimal value of operating time to predetermined maintenance \( t_{po} \) [1] it is possible to calculate from equation (15) which is analogical to equation (1) and (4) and using three parameters Weibull distribution function, we obtain:

\[
c(t_p) = \frac{C_p + L_c F(t_p)}{T(t_p)} = \frac{C_p + L_c \left(1 - \exp\left(-\frac{(t_p - \gamma)^{s}}{\beta}ight)\right)}{t_p \exp\left(-\frac{(t_p - \gamma)^{s}}{\beta}\right)} \]

(15)

For solution of equation (14) and (15) it is possible to use a numerical method, e.g. to use MS Excel.

4. Numerical solution

We have simulated the life \( t_f \) of 44 objects to failure and their technical state (diagnostic signals) \( S_f \) shortly before failure, including costs and losses. Value of diagnostic signal may represent the ratio of a two values of variable, therefore, the value presented by diagnostic signal is a dimensionless number. There were obtained input data – see Table 1.

Using input reliability and economic data regarding life time \( t_f \) from Table 1 and software http://wessa.net/rwasp_fitdistrweibull.wasp we obtained mean operating time to failure (MOTTF), standard deviation (SD) \( \sigma \) and parameters \( \alpha \), \( \beta \) and \( \gamma \) of the Weibull distribution function – see Table 2.

Using input reliability data regarding technical state (diagnostic signal) \( S_f \) from Table 1 and software http://wessa.net/rwasp_fitdistrweibull.wasp, we obtained average diagnostic signal (technical state) \( \bar{S}_f \), standard deviation (SD) \( \sigma_S \) and parameters \( \alpha_s \), \( \beta_S \) and \( \gamma \) of the Weibull distribution function – see Table 3.

---

Unit costs of preventive maintenance and failure risk

\[ L_f (1 - \exp(-\frac{t_p - \gamma_p}{\beta_f})) \] versus operating time (period) of preventive predetermined maintenance we can calculate by means of equation (15) – see some results in Table 4 and on Fig. 2.

\[ c(\text{Spo}) = C_{pr} + L_f (1 - \exp(-\frac{S_p - \gamma_p}{\beta_p})) + c_f \] (16)

Now we can calculate optimal diagnostic signal (technical state) for restoration \( \text{Spo} \) using equation (4) substituting Weibull distribution function to equation (16) and by application MS Excel, we can calculate unit costs \( c(\text{Spo}) \) of preventive maintenance, diagnostics and failure risk versus diagnostic signal for predictive maintenance, optimal diagnostic signal \( \text{Spo} \), (technical state) for restoration and mean operating time versus diagnostic signal for predictive maintenance.

\[ \text{Restoration signal} = \left( \frac{1}{n} \sum_{i=1}^{n} t_i(\text{Spo}) + \sum_{i=1}^{n} t_j(\text{Spo}) \right) \] – see Table 5 and Fig. 3.

Knowledge of optimal diagnostic signal \( \text{Spo} \) (see Fig. 3) is very important for the design of predictive maintenance. We can very easily indicate dispositional operating time \( t_j(\text{Spo}) \) according to equation (5) to be able to plan the maintenance of an object.

Now we use MS Excel to compute mean life \( ET \) of the objects that have undergone preventive maintenance after the optimal interval \( t_{p,o} = 1,076.7 \) hours (according to the equation (15)) by the Weibull distribution function with parameters \( \alpha, \beta \) and \( \gamma \) using numerical method of \( R(t) \) integration.

\[ ET = \frac{\int_{0}^{t_{p,o}} R(x)dx}{1 - R(t_{p,o})} = \frac{\gamma_t + \int_{t_{p,o}}^{\infty} \exp(-\frac{t - \gamma_p}{\beta_f}) dt}{1 - \exp(-\frac{t_p - \gamma_p}{\beta_f})} = 1,076.72 \] (17)

Numerical calculation (for the Weibull distribution function with parameters \( \alpha = 1.823, \beta = 971.466 \) and \( \gamma = 506 \)) of \( R(t) \) is done according to equations (9) and (10) and of \( R(t) \) is done according to equation (18) – see Fig. 4.

\[ R(t) = \exp(-\frac{t - \gamma_p}{\beta_f}) \] (18)

From this figure it is clear that the object with predetermined maintenance has a much better reliability function \( R(t) \) than the same object maintained after failure (reliability function \( R(t) \)).

**Fig. 4. Reliability functions \( R(t) \) (object is running to failure without preventive maintenance) and \( R(t) \) (preventive predetermined maintained object) versus operating time**

### 5. Conclusion

Authors offer a tool for maintenance managers which represents general methods of calculating the optimal interval for predetermined maintenance and the optimal diagnostic signal for predictive maintenance – equations (1) and (15). Further, the authors deduced equations for mean life and probability reliability function of predetermined maintained machine objects and equations for predictive maintenance optimization – equations (10), (12) and (14). Authors prove that preventive maintenance improves reliability. From equation (14) it is clear that mean life of preventive predetermined maintained objects \( ET > \int_{0}^{t_{p,o}} R(x)dx \) (mean life of corrective maintained objects) for \( t_{p,o} < \infty \). Numerical solution presented graphically on Fig. 4 also shows that reliability of preventive predetermined maintained objects decreases more slowly than the reliability of objects which are running to failure.

The example shows an application of the proposed mathematical model on a virtual machine object. When we replace the component after failure, the \( \text{MOTTF} = 1,363 \) hours and production losses due to the failure risk \( L_f = 11,000 \) EUR and unit costs of preventive maintenance and failure risk, then \( c(\text{MOTTF}) = 15.4 \) EUR/hour. When we introduce predetermined maintenance (for \( t_{p,o} = 1,077 \) hours) of the object, the \( \text{MOTTF} \) increases to \( ET = 3,360 \) hours and unit costs of preventive maintenance and failure risk decrease to 13.4 EUR/hour – see Fig. 2 and Fig. 4.

When we introduce predictive maintenance on the same object using the derived equation (16), we obtained optimal diagnostic signal \( \text{Spo} = 3.4 \) and unit costs \( c(\text{Spo}) = 11.6 \) EUR/hour. If we compare these unit costs with unit costs of periodic maintenance \( c(\text{Spo}) = 13.4 \) EUR/hour, we see that this predictive maintenance strategy brings economical effect of 1.8 EUR/hour. We can see the comparison of all results of the example of chosen maintenance policies from Table 6.
The best maintenance policy from point of unit costs for this example is a predictive maintenance.

The benefit of the proposed mathematical models is not only the ability to compute the optimal interval of predetermined maintenance and optimal diagnostic signal for predictive maintenance, but also to provide quantitative proof that preventive predetermined maintenance increases operational reliability of machine objects. The decision lies with maintenance specialists, whether or not they adopt and apply these models and methods for improving maintenance effectiveness of industry production equipment.
